This is a cheat sheet for USAAAO

## 1 Orbital Dynamics

### 1.1 Newton Gravity Law

$$F_g = \frac{GMm}{r^2}$$

This is known as the *Inversed-Squared* law of gravity.  $G$  is the Gravitational Constant.

#### 1.1.1 Gravity Potential Energy: Point Mass

Assuming the potential energy at infinity is *zero*, by integrating the gravity law, we have the potential energy at  $R$ :

$$U = \int_{\infty}^R \frac{GMm}{r^2} dr = -\frac{GMm}{R}$$

Therefore the *Sun* can be visualized as a *Gravitational Well*, in which the deeper you get, the less energy you have.

#### 1.1.2 Gravity Potential Energy: Uniform Ball

A ball with mass  $M$  and radius  $R$ , assuming uniform density:

$$\rho = \frac{M}{\frac{4}{3}\pi R^3}$$

The potential energy is:

$$\begin{aligned} U &= \int_0^R dU = \int_0^R -\frac{GM(r)dm}{r} \\ &= \int_0^R -\frac{G \cdot \frac{4}{3}\pi r^3 \rho \cdot 4\pi r^2 dr \rho}{r} \\ &= -\frac{3GM^2}{R^6} \int_0^R r^4 dr \\ &= -\frac{3}{5} \frac{GM^2}{R} \end{aligned}$$

**6** Together with *virial theorem*:  $\langle K \rangle = -\frac{1}{2}\langle U \rangle$ , one can link the observational properties (velocities->kinetic energy) to its mass

## 1.2 Conservation of Momentum

### Examples:

Without the effects of *force*, the momentum of the system is conserved:

$$\vec{P} = \sum_m \vec{p} = \sum_m m\vec{v} = \text{const}$$

## 1.3 Conservation of Angular Momentum

### Examples:

Without the effects of *torque*, the angular momentum of the system (referenced at a give point) is conserved

$$\vec{L} = \sum_m \vec{l} = \sum_m \vec{r} \times m\vec{v} = \text{const}$$

## 1.4 Conservation of Energy

The total energy: Kinetic+Potential is **conserved** for planets:

$$E = K + U = \frac{1}{2}mv^2 - \frac{GMm}{r}$$

For a ellipse orbit with semi-major axis  $a$ : (Derivation: Conservation of energy at aphelia and perihelia)

$$E = -\frac{GMm}{2a} = \frac{1}{2}mv^2 - \frac{GMm}{r}$$

### 1.4.1 Orbital Energy

$E = -\frac{GMm}{2a}$  is known as the *orbital energy*. One immediately notices three properties:

- $E$  is *negative* for ellipse ( $a > 0$ ), *zero* for parabola ( $a = \infty$ ), *positive* for hyperbola ( $a < 0$ )
- Increase in *orbital energy* will increase  $a$  until it becomes a parabola, or even hyperbola
- A meteorite is *trapped* when  $E < 0$ , it *escapes* when  $E \geq 0$ .

### 1.4.2 Vis-Viva Equation

Due to the conservation of orbital energy, one calculate velocity based on distance  $r$ :

$$v = \sqrt{GM \left( \frac{2}{r} - \frac{1}{a} \right)}$$

This is known as the *vis-viva* equation. The *escape* velocity is:

$$v_{\text{escape}} = \sqrt{\frac{2GM}{r}}$$

**Examples:** 2021-Q15

### 1.4.3 Viral Theorem

In statistical mechanics, people are often interested in the averaged behavior of an ensemble of particles, one of the most important results is the *viral theorem*:

$$\langle K \rangle = -\frac{1}{2}\langle U \rangle$$

And therefore the total energy:

$$\langle E \rangle = \langle K \rangle + \langle U \rangle = -\langle K \rangle = \frac{1}{2}\langle U \rangle$$

**Examples:** 2021-Q9

## 1.5 Kepler's Law

**Examples:** 2023-Q21

### 1.5.1 First Law

*The orbit of a planet is an ellipse with the Sun at one of the two foci.*

### 1.5.2 Second Law

*line segment joining a planet and the Sun sweeps out equal areas during equal intervals of time.*

This is effectively the *Conservation of Angular Momentum*, because:

- For a small object orbiting a central star, the *Gravity force* is point towards the star, therefore the change in angular momentum:

$$d\vec{L} = \vec{r} \times \vec{F}_g = 0$$

And the angular momentum:

$$\vec{L} = \vec{r} \times m\vec{v}$$

is conserved.

- Constant  $\vec{L}$  is identical to \* sweeps out equal areas during equal intervals of time\*

$$\vec{r} \times m \vec{v} dt \propto \vec{r} \times \vec{v} dt$$

is the small change in the area

### 1.5.3 Third Law

The square of a planet's orbital period is proportional to the cube of the length of the semi-major axis of its orbit.

Simple derivation can be inferred from circular orbit, where the **centrifugal force balances the gravity force** ( $v\omega = v^2/r = \omega^2 r$  is known as the **centrifugal acceleration**):

$$\frac{GMm}{a^2} = m \frac{v^2}{a} = m \omega^2 a = m \left( \frac{2\pi}{T} \right)^2 a \frac{GM}{4\pi^2} = \frac{a^3}{T^2}$$

## 1.6 Sidereal Day and Solar Day

**Examples:** 2020-Q12;

We denote sidereal day as  $t_{sid}$  and Solar Day as  $t_{sol}$ , we have:

$$t_{sid} = \frac{2\pi}{\omega_0}$$

$$t_{sol} = \frac{2\pi}{\omega_0 - \omega_1 \cos \theta}$$

where  $\omega_0$  is the angular velocity of the planet's rotation, and  $\omega_1$  is the angular velocity of orbital revolution,  $\theta$  is the tilt angle.

## 2 Celestial Coordinates and Time

**Examples:** 2023-Q1|17|18; 2022-Q24|25|28|30

### 2.1 Trigonometry

#### 2.1.1 Length of Arc

Circumference:  $2\pi r$

Length of Arc:  $\theta r$

Figure 1: Trigonometry

#### 2.1.2 Law of Cosine

$$a^2 = b^2 + c^2 - 2bc \cos \alpha$$

$$b^2 = a^2 + c^2 - 2ac \cos \beta$$

$$c^2 = a^2 + b^2 - 2ab \cos \gamma$$

Derivation:

$$\vec{BC} = \vec{AC} - \vec{AB}$$

$$\begin{aligned} |\vec{BC}|^2 &= |\vec{AC} - \vec{AB}|^2 \\ &= |\vec{AC}|^2 + |\vec{AB}|^2 - 2\vec{AC} \cdot \vec{AB} \\ a^2 &= b^2 + c^2 - 2bc \cos \alpha \end{aligned}$$

#### 2.1.3 Law of Sine

$$\frac{a}{\sin \alpha} = \frac{b}{\sin \beta} = \frac{c}{\sin \gamma}$$

### 2.2 Spherical Trigonometry

#### 2.2.1 Spherical Law of Cosine

$$\cos a = \cos b \cos c + \sin b \sin c \cos A$$

$$\cos b = \cos c \cos a + \sin c \sin a \cos B$$

$$\cos c = \cos a \cos b + \sin a \sin b \cos C$$

#### 2.2.2 Spherical Law of Sine

$$\frac{\sin A}{\sin a} = \frac{\sin B}{\sin b} = \frac{\sin C}{\sin c}$$

#### 2.2.3 Area of the Spherical Triangle

$$\text{Area of triangle} = A + B + C - \pi \text{Total Area} = 4\pi$$

Figure 2: Spherical Trinometry

Figure 3: Circumpolar

## 2.3 Celestial Coordinate

### 2.3.1 Circumpolar

$$90 - \delta < \lambda$$

$\lambda$  is latitude,  $\delta$  is declination

## 3 Telescope & Star Magnitudes

### 3.1 Parallax

**Examples:**

One *parsec*  $\approx 3.26$  *ly* is the parallax of the distant star from a triangle of 1AU and 1 arcsec

Some confusing notations:

- *mac*: micro-arcsec =  $10^{-3}$  *arcsec*
- *Mpc*: Million-parsec =  $10^6$  *pc*

### 3.2 The Airy Spot

**Examples:** 2022-Q6

Due to the diffraction of light, the *best-focused spot* of light has a limited angular size.

$$\sin \theta \approx \theta \approx 1.22 \frac{\lambda}{d}$$

where  $\lambda$  is the light wavelength,  $d$  is the diameter of the lens. To **differentiate** two light source, they have to be  $\theta$  away from each other.

## 3.3 Telescope Parameters

**Examples:** 2021-Q13, 2023-Q2|Q24

### 3.3.1 $f$ number (focal ratio)

The focal ratio is the ratio between the focal length  $f$  and the diameter of the aperture  $d$ :

$$N = \frac{f}{d}$$

This number is usually denoted as  $f/N$ .

For example,  $f/2$  means  $f = 2d$ , the *larger the number, the worse the telescope*.

### 3.3.2 Magnification

The magnification:

$$m = f_o / f_e$$

is the ratio between the focal length of *objective* and *eyepiece* lens.

## 3.4 The Apparent and Absolute Magnitude

**Examples:** 2023-Q2|13; 2022-Q8|18|20; 2021-Q22|23; 2020-Q13; 2019-Q13, 2018-Q13|21

Figure 4: Parallax

Figure 5: Airy Pattern

### 3.4.1 Magnitude and Flux

The ultimate physical carrier of light is the flux of photons (or electric-magnetic field), which follows the *inversed-squared law*. Magnitude is a *representation* of the *relative* amount of flux. The definition is that:

Five unit of *magnitude* = 100 difference in *flux*

$$100^{\frac{m_1 - m_2}{5}} = \frac{F_2}{F_1}$$

This can be rewritten in terms of distance (for same type of star):

$$10^{\frac{m_1 - m_2}{5}} = \frac{d_1}{d_2}$$

And in log10 in terms of distance:

$$m_1 - m_2 = 5 \log_{10} d_1 - 5 \log_{10} d_2$$

### 3.4.2 Absolute Magnitude $M$

The apparent magnitude of a star measured at  $10pc$  ( $\log_{10}(10pc) = 1$ ):

$$M = m - 5 \log_{10}(d_{pc}) + 5$$

### 3.4.3 Extinction

Due to the existence of dust, the light can dim:

$$m - M = 5 * \log(d) - 5 + a_V * d$$

Where  $a_V$  is the interstellar extinction in the unit of *mag/pc* or *mag/kpc*

**Examples:** 2021-Q23, 2019-Q13

## 4 Special Relativity, Hubble's Law & Red Shift

### 4.1 Hertzsprung–Russell diagram

### 4.2 Special Relativity

If the velocity is comparable to the speed of light  $c$ , the relativity effects can not be ignored.

Figure 6: H-R Diagram

#### 4.2.1 Mass-Energy Equation

**Examples:** 2023-Q11, 2022-Q12|15, 2021-Q20, 2020-Q15

The mass and energy is equivalent:

$$E = mc^2$$

The loss of mass is identical to the loss of energy. This is the ultimate source of energy in the universe: *Fusion in the stars.*

#### 4.2.2 Lorentz Coefficient

$$\gamma = \frac{1}{\sqrt{1 - v^2/c^2}}$$

For a moving body, the time flow is slower “*Time dilation*”: ( $S'$  is the moving frame)

$$\Delta t' = \gamma \Delta t$$

The “*length contraction*”:

$$\Delta x' = \frac{\Delta x}{\gamma}$$

**Examples:** 2023-Q15,

### 4.3 Hubble’s Law & Red Shift

**Examples:** 2023-Q27; 2022-Q29; 2021-Q8|12|26

The universe is constantly expanding with a coefficient  $H_0 = 70 \text{ km/s/Mpc}$ , the expanding speed is:

$$v = H_0 D$$

The resulting “red-shift velocity” is **defined** to be:

$$v_{rs} = cz$$

where  $z$  is the red shift. In low velocity case, this can be related to the real red-shift in observed wavelength using the *Fizeau-Doppler Formula*:

$$z = \frac{\lambda_o}{\lambda_e} - 1 = \sqrt{\frac{1 + \frac{v}{c}}{1 - \frac{v}{c}}} - 1 \approx \frac{v}{c}$$

where  $\lambda_o$  and  $\lambda_e$  is the observed and emitted wavelength. Since the speed of light is constant, this can also be used to calculate the change in frequency:

$$\frac{\nu_e}{\nu_o} = \sqrt{\frac{1 + \frac{v}{c}}{1 - \frac{v}{c}}}$$

#### 4.3.1 Critical Density of the Universe

Replace the escape velocity with the speed of the light from Hubble’s expansion:

$$c = H_0 r = \sqrt{\frac{2GM}{r}}$$

We have:

$$\rho = \frac{M}{\frac{4}{3}\pi r^3} = \frac{3H_0^2}{8\pi G} \simeq 9.22 \times 10^{-27} \text{ kg} \cdot \text{m}^{-3}$$

## 5 MISC

#### 5.0.1 Signal to Noise Ratio

Proportional to  $\sqrt{N}$ , where  $N$  is the number of measurements or exposure time

**Examples:** 2022-Q27

#### 5.0.2 Energy of E&M Wave

Poynting Flux:

$$\vec{S} = \vec{E} \times \vec{B}$$

is *independent* of frequency

## 6 Constants and Notations

### 6.1 Constants

1. The absolute magnitude of the Sun: 4.83
2. Age of the Universe: 13.3 Billion years
3. Visible wavelength: 310 nm (ultraviolet) - 1100 nm (infrared)

### 6.2 Notations

1. Length:

| Notation      | Length [m] |
|---------------|------------|
| pm            | $10^{-12}$ |
| $\text{\AA}$  | $10^{-10}$ |
| nm            | $10^{-9}$  |
| $\mu\text{m}$ | $10^{-6}$  |
| mm            | $10^{-3}$  |
| cm            | $10^{-2}$  |
| km            | $10^3$     |
| Mm            | $10^6$     |

Figure 7: Lengths
